Do I need to use a driver? Or can I use a command? Any code suggestions are welcome. Thank you. A: The Intel 8265BT (e7ce91a8) Bluetooth module does not provide any way to stop it. The Linux kernel driver btusb provides several possible methods. btusb_stop_device() seems to be the best one. It stops the BLE module completely (it will report that it is stopped, as well). Try something like this: btusb_stop_device(bus), With int bus = -1; for finding the bus number of the Bluetooth bus. Alternatively, try the btusb_start_device() method, but it will not stop the module. It is likely that you will not see any change in the status if the device is stopped, as that information is not in 82157476af
